What can we (AI) do to help?

The **dimension** of the economist's problem space has exploded

We can develop ML to navigate this space: **stay safe and automate**

We can also build new econometrics via deep structure

Example: Demand System

Suppose that you have transactions ' t ' on products ' j '.

Write the quantity bought ' q ' as

$$q_{tj} = \alpha_j(\mathbf{d}_t) + \gamma_j \log p_{tj} + e_{tj}$$

a function of utility we can ($\alpha_j(\mathbf{d}_t)$) and can't (e_{tj}) see, plus price p_{tj} .

You need to have a model like this to target customers or set prices.

But it's a system!

For example: There many different products

Demand for j depends on **substitutes** and **complements**

Or: where does price come from?

$$\log p_{tj} = \varphi_t(\mathbf{c}_j) + \psi_j q_{tj}^* + v_{tj}$$

and the *demand system* is in equilibrium when $q_{tj}^* = q_{tj}$

This equilibrium introduces `price endogeneity': $\mathbb{E}[p_{tj} e_{tj}] \neq 0$

Sometimes it's just regression

If we treat ε_{tj} as independent this is a prediction problem
e.g., model store transactions with covariates \mathbf{x}_{tj} as

$$\mathbb{E} \log q_{tj} = \mathbf{x}_{tj}' \boldsymbol{\beta} + \log p_{tj} \mathbf{x}_{tj}' \boldsymbol{\gamma}$$

Elasticities:

one shared: $x_{tj} = 1$

brand-specific: $x_{tjk} = \mathbb{1}_{[k=j]}$

\mathbf{x}_{tj} = featurized description

$$\frac{dq}{dp} \frac{p}{q} = -0.23$$

Moving inside a demand system (AIDS)

It's *almost* ideal:

$$\mathbf{s}_t = \boldsymbol{\alpha} + \boldsymbol{\Gamma} \log(\mathbf{p}_t) + \boldsymbol{\beta} \log \frac{e_t}{\phi_t} + \boldsymbol{\varepsilon}_t$$

s_{tj} is the **budget share** for product j in basket t and e_t is the budget
($e_t = \sum_j \$_{tj}$ and $s_{tj} = \$_{tj}/e_t$)

ϕ_t is the **translog price index** $\sum_j \log p_{tj} [\alpha_j + \sum_k \gamma_{jk}^* \log p_{tk}]$
(which we will replace with a plug-in for estimation)

This is meaningful after aggregation, and **we can actually estimate it**

Factorizing Γ

The price terms are key to finding complements and substitutes

$$\mathbb{E}s_{tj} = \alpha_j + \sum_k \gamma_{jk} \log p_{tj} + \beta_j \frac{e_t}{\phi_t}$$

Γ is $J \times J$, so we need to reduce dimension if J is going to go big

One option: square matrix factorizations from word/prod embedding

$$\mathbf{\Gamma} = \mathbf{UV}' + \mathbf{VU}' + \mathbf{D} \text{ where } \mathbf{u}_j, \mathbf{v}_j \text{ are } S\text{-vectors and } \mathbf{D} \text{ is } J\text{-diagonal}$$

(AIDS implies restrictions: $\gamma_{jk} = \gamma_{kj}$, $\sum_j \gamma_{jk} = \sum_j \gamma_{kj} = \sum_j \beta_j = 0$)

Product Embeddings

substitutes (synonyms) are close in the same vector space
complements (topical words) are close across vector spaces

Beer

We fit on store-week totals.

Translate the γ_{jk} values into [compensated] elasticities as

$$\frac{\gamma_{jk}}{\bar{s}_j} - \bar{s}_k - \mathbb{1}_{[k=j]}$$

Elasticity matrix (omitting diagonal)

But wait... it's still a system

$$s_t = \alpha + \Gamma \log(\mathbf{p}_t) + \beta \log \frac{e_t}{\phi_t} + \mathbf{e}_t$$

Recall: where does price come from?

$$\log p_{tj} = \varphi_t(\mathbf{c}_j) + \psi_j q_{tj}^* + v_{tj}$$

and the *demand system* is in equilibrium when $q_{tj}^* = q_{tj}$

This equilibrium introduces 'price endogeneity': $\mathbb{E}[p_{tj} e_{tj}] \neq 0$

Endogenous Errors

$$y = g(p, \mathbf{x}) + e \text{ and } \mathbb{E}[p e] \neq 0$$

If you estimate this using naïve ML, you'll get

$$E[y|p, \mathbf{x}] = E_{e|p}[g(p, \mathbf{x}) + e] = g(p, \mathbf{x}) + E[e|t, \mathbf{x}]$$

This works for **prediction**. It doesn't work for **counterfactual** inference:

What happens if I change p independent of e ?

— Prediction — Counterfactual Prediction

Instrumental Variables (IV)

In IV we have a special $z \perp e$ that influences policy p but not response y .

- Supplier costs that move price independent of demand (e.g., fish, oil)
- Any source of treatment randomization (intent to treat, AB tests, lottery)

Instrumental Variables (IV)

The *exclusion structure* implies

$$E[y|x, z] = E[g(p, x) + e|x, z] = \int g(p, x) dP(p|x, z)$$

So to solve for *structural* $g(p, x)$ we have a new learning problem

$$\min_{g \in G} \sum \left(y_i - \int g(p, x_i) dP(p|x_i, z_i) \right)^2$$

$$\min_{g \in G} \sum \left(y_i - \int g(p, x_i) dP(p|x_i, z_i) \right)^2$$

You might have seen 2SLS:

$$p = \beta z + v \text{ and } g(p) = \tau p \text{ so that } \int g(p) dP(p|z) = \tau \hat{p} = \tau \hat{\beta} z$$

So you first regress p on z then regress y on \hat{p} to recover $\hat{\tau}$.

This requires strict assumptions and homogeneous treatment effects.

$$\min_{g \in G} \sum \left(y_i - \int g(p, x_i) dP(p|x_i, z_i) \right)^2$$

We can target this integral loss function directly with flexible g and P .

Brute force version

- Fit conditional distributions $\hat{P}(p|x_i, z_i)$.
- Generate $\{\hat{p}_{ib}\}_{b=1}^B \sim \hat{P}(p|x_i, z_i)$ for each i .
- Train \hat{g} to minimize $[y_i - B^{-1} \sum_b g(\hat{p}_{ib}, x_i)]^2$.

Turns IV into two ML tasks: we can use DNNs for both \hat{P} and \hat{g} .

Learning to love Deep Nets

First Stage is out-of-the-box ML: learn $P(p|x_i, z_i)$

e.g., DNN fits distribution to maximize likelihood for a mixture of Gaussians.

The second stage involves an integral loss function

Brute force just samples from $\hat{P}(p|x_i, z_i)$ to evaluate

$$\min_{\theta \in \Theta} \frac{1}{N} \sum_i \left(y_i - \frac{1}{B} \sum_b g(\hat{p}_{ib}, x_i; \theta) \right)^2, \quad \hat{p}_{ib} \sim \hat{P}(p|x_i, z_i)$$

Instead, *Stochastic Gradient Descent*: optimize via *unbiased* gradient estimates based upon mini-batch sample of the full dataset.

We can do SGD by pairing each observation with *two* treatment draws

$$\nabla g(\theta) \approx (y_i - g(\hat{p}_{i1}, x_i; \theta)) g'(\hat{p}_{i2}, x_i; \theta)$$

Linear Demand, Heterogeneous Effects

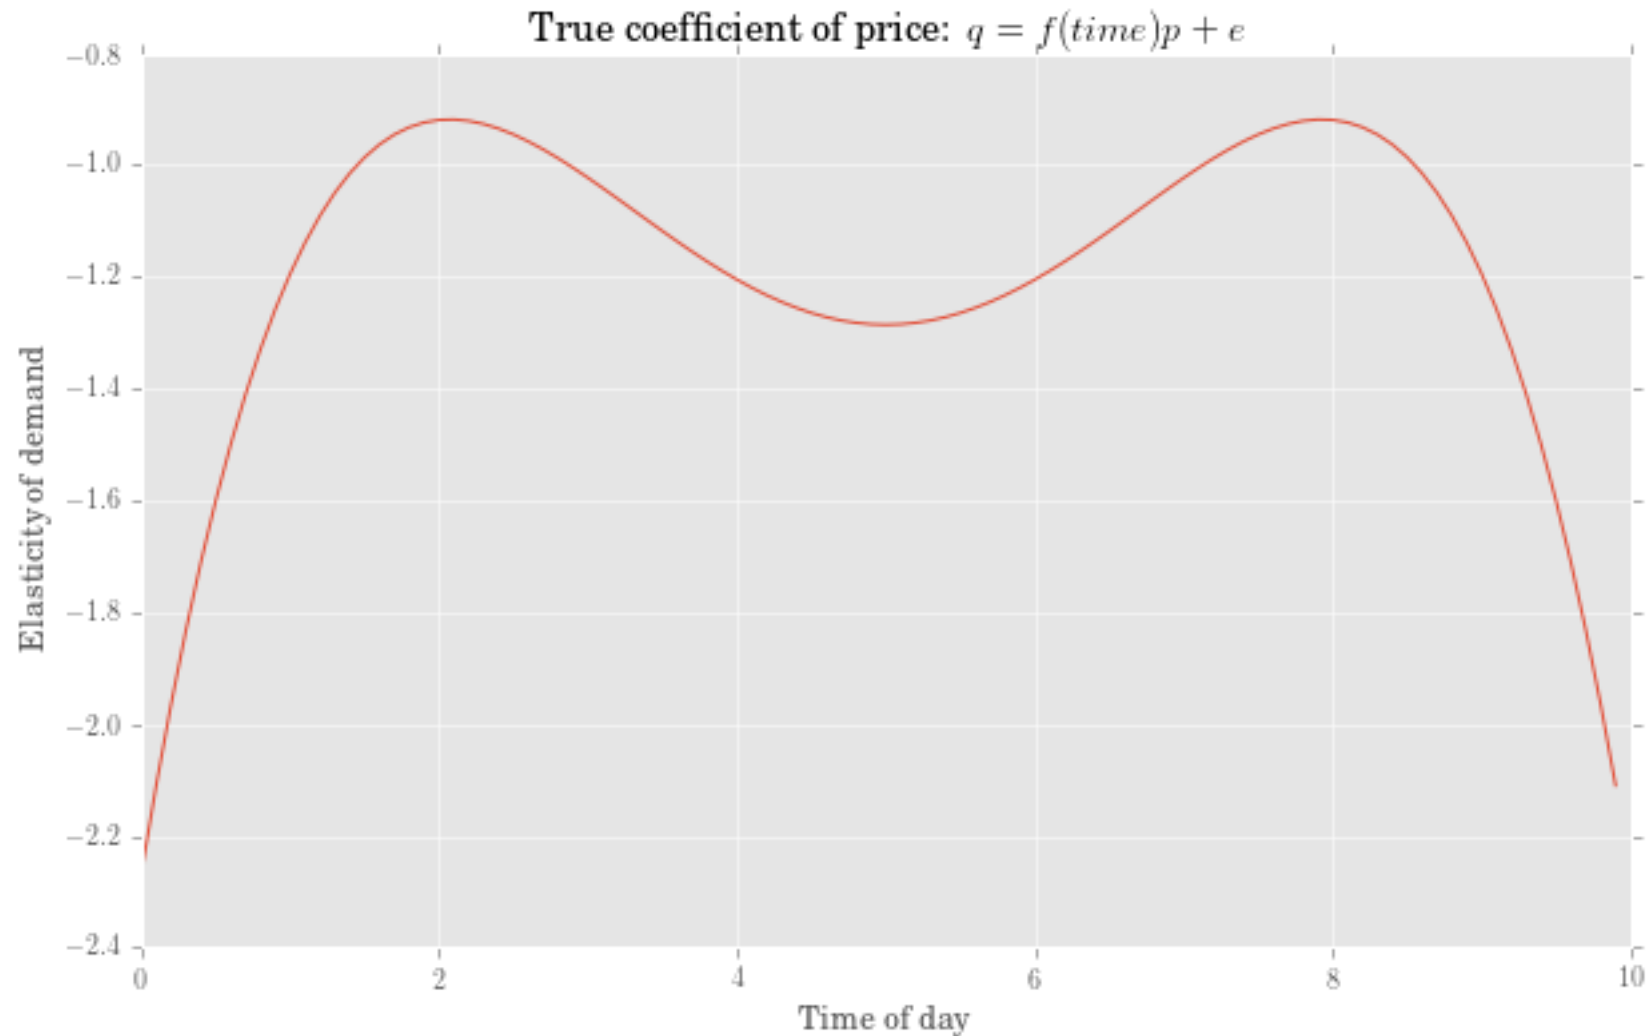

Figure B: $x=2.300000$

Ads Application

Taken from Goldman and Rao (2014)

We have 74 mil click-rates over 4 hour increments for 10k search terms

Treatment: **ad position 1-3**

Instrument: **background AB testing**

Covariates: **search text and time**

Average Treatment Effects

Heterogeneous Treatment Effects

Economics and Artificial Intelligence

We have a track record pointing ML at questions of science + causation.

We're going to replicate this success at scale on unstructured data

We use economic theory to build systems of tasks that can be addressed with Deep nets and other state-of-the-art ML.

This is the construction of systems for Artificial *Economic* Intelligence.
