Tell me about your problem and I'll help you find the solution you need.

how do I upgrade windows>

Here's what I think you are asking about: *How to install or upgrade to Windows 10.* Is that correct?

Yes

Okay, you're looking for some info on Windows 10. What would you like to do?

Upgrading to Windows 10

#### How to get Windows 10

- 1. Windows 10 is available by buying a new device or a full version of the software.
- 2. The Windows 10 free upgrade through the Get Windows 10 (GWX) app ended on July 29, 2016. Click here to find more information about upgrading to Windows 10

## THE WALL STREET JOURNAL

**TECH** 

#### Microsoft Aims to Make Business AI Cheaper, Faster, Simpler

New line of software will take on IBM, others, in growing artificial-intelligence market

By Ted Greenwald

Sept. 25, 2017 9:00 a.m. ET

Microsoft Corp. plans Monday to unveil its first product in a new line of software aimed at taking on International Business Machines Corp. and others in the growing market to apply artificial intelligence to everyday business needs.

The new product, a customer-service virtual assistant, is designed to let people

## The Economics of Al

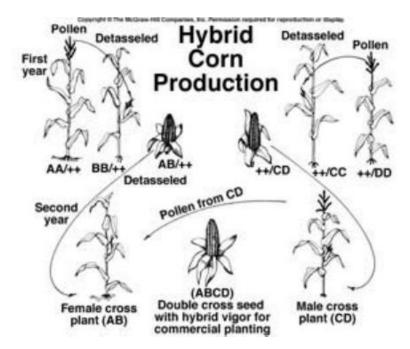

DNNs are GPT and 'method for invention'

- Broad impact, up and down the value chain
- Gets better, faster, and cheaper in time
- Can suffer from underinvestment
- Productivity gains lag invention

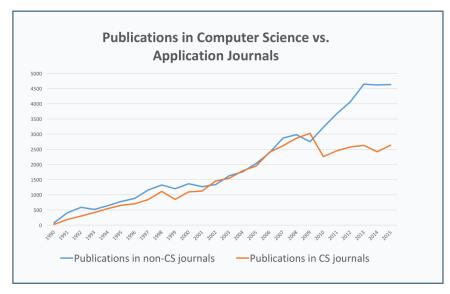

Automation, inequality, skill acquisition

Data ownership, markets, and privacy

High-info contracts and outcome pricing

Al research in computer science journals vs. other application sectors.

#### What about the impact of AI on the practice of Econom[etr]ics?

# Susan Athey:

#### Predictions for Economics

- Adoption of off-the-shelf ML methods for their intended tasks (prediction, classification, and clustering, e.g. for textual analysis)
- Extensions and modifications of prediction methods to account for considerations such as fairness, manipulability, and interpretability
- Development of new econometric methods based on machine learning designed to solve traditional social science estimation tasks, e.g. causal inference
- Increased emphasis on model robustness and other supplementary analysis to assess credibility of studies
- Adoption of new methods by empiricists at large scale
- Revival and new lines of research in productivity and measurement

- New methods for the design and analysis of large administrative data, including merging these sources
- Increase in interdisciplinary research
- Changes in organization, dissemination, and funding of economic research
- "Economist as engineer" engages with firms, government to design and implement policies in digital environment
- Design and implementation of digital experimentation, both one-time and as an ongoing process, in collaboration with firms and government
- Increased use of data analysis in all levels of economics teaching; increase in interdisciplinary data science programs
- Research on the impact of AI and ML on economy

#### Econometrics breaks systemic questions into sets of prediction tasks

- Prediction after controlling for confounders
- Two-stage prediction with IVs
- Heterogeneous treatment effect prediction
- Structural equation systems

Machine Learning can automate and accelerate tasks in these applied econometric workflows

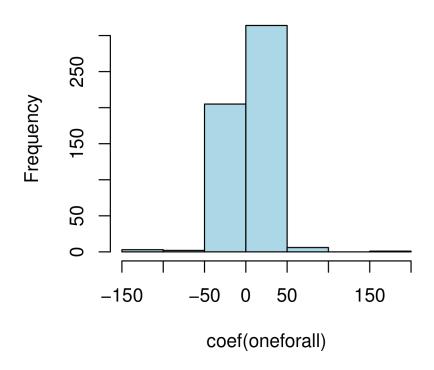

## Example: short-term price elasticity

If I drop price 1%, by what % will quantity sold increase? Problem: both prices and sales respond to underlying demand Need a causal effect of price on sales, not their co-movement

#### **Beer Data**

A single shared elasticity gives tiny -0.23 Separate elasticity for each: noisy zeros

We need to group the products together using brand, pack, etc.

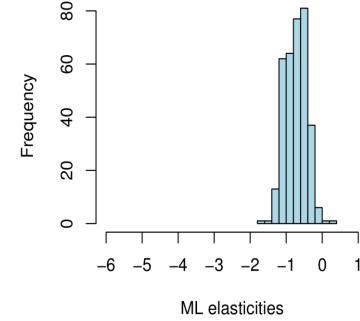

### Beer Elasticity

Say  $w_{ik} = 1$  if word k is in description for beer b

@transaction t: 
$$\log y_{bt} = \alpha_b + \delta_t + \mathbf{w}_b' \mathbf{\tau} + \gamma_b \log p_{bt} + \varepsilon_{bt}$$
,  $\gamma_b = \mathbf{w}_b' \mathbf{\psi}$ 

Creates a large number of parameters Just throw it all in a lasso?

Yields unbelievably small elasticities
This is not a pure prediction problem

The naïve ML conflates two problems: selecting controls and predicting response after controlling for confounders.

Instead, use Orthogonal ML (Chernozhukov et al, 2016 and earlier)

- Estimate nuisance functions orthogonal to  $\gamma$  in its conditional score.
- Then estimation for  $\gamma$  is robust to slow-learned nuisance functions.

Price sensitivity estimation breaks into two ML tasks:

- 1. Predict prices from the demand variables:  $p \sim x$
- 2. Predict sales from the demand variables:  $y \sim x$

(use data splitting to get honest residuals)

Plus a final regression:

$$E(y-\widehat{y}(x)) = \gamma \times (p-\widehat{p}(x))$$

### Orthogonal ML for Beer

For the final fit, interact text with residuals to get text-dependent elasticity

The text encodes a natural hierarchy

Many beers are IPA or Cider or Draught

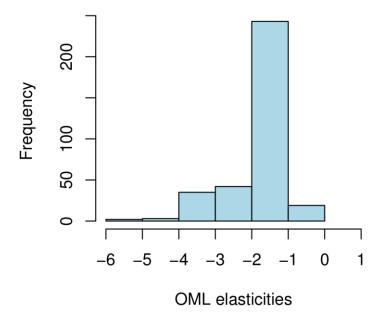

But individual brands also load; e.g., Pyramid or Elysian

#### Most price sensitive

- > names(sort(el)[1:5])
- [1] "GUINNESSS DRAUGHT 6PK BTL
- [2] "GUINNESS DRAUGHT 4PK CAN
- [3] "PYRAMID OUTBURST IMP IPA 6PK
- [4] "ELYSIAN IMPORTAL IPA 6PK
- [5] "PYRAMID OUTBURST IMP IPA 12PK

#### Least Price Sensitive

- > names(sort(-el)[1:5])
- [1] "2 TOWNS CRISP APPLE CIDER
- [2] "2 TOWNS BAD APPLE CIDER
- [3] "ATLAS BLKBRY APPLE CIDER
- [4] "D'S WICKED BAKED APPLE CIDER
- [5] "D'S WICKED GREEN APPLE CIDER

#### Econ + ML

This is what econometricians do: they break systems into measurable pieces Another common example: Instrumental Variables

Endogenous errors:

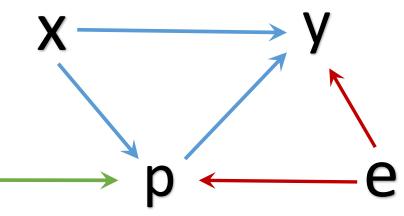

$$y = g(p, x) + e$$
 and  $\mathbb{E}[pe] \neq 0$ 

If you estimate this using naïve ML, you'll get

$$E[y|p,x] = E_{e|p}[g(p,x) + e] = g(p,x) + E[e|p,x]$$

But, with instruments...

Instrumental Variables (IV)

The exclusion structure implies

$$\mathbb{E}[y|x,z] = \int g(p,x)dF(p|x,z)$$

You can observe and estimate  $\widehat{\mathbb{E}}[y|x,z]$  and  $\widehat{F}(p|x,z)$ 

 $\Rightarrow$  to solve for *structural* g(p, x) we have an inverse problem.

$$\min_{g \in G} \sum \left( y_i - \int g(p, x_i) dF(p|x_i, z_i) \right)^2$$

**2SLS:**  $p = \beta z + \nu$  and  $g(p) = \tau p$  so that  $\int g(p)dF(p|z) = \tau \mathbb{E}[p|z]$ So you first regress p on z then regress y on  $\hat{p}$  to recover  $\hat{\tau}$ .

Sieve:  $g(p, x_i) \approx \sum_k \gamma_k \varphi_k(p, x_i)$ ,  $\mathbb{E}_F[\varphi_k(p, x_i)] \approx \sum_j \alpha_{kj} \beta_j(x_i, z_i)$ 

Also Blundell, Chen, Kristensen, , Chen + Pouzo, Darolles et al, Hall+Horowitz

$$\min_{g \in G} \sum \left( y_i - \int g(p, x_i) dF(p|x_i, z_i) \right)^2$$

Instead, we use DNNs to target the integral loss function directly

- First, fit  $\widehat{F}$  using a network with multinomial response
- Second (preferably on another sample) fit  $\hat{g}$  following

$$\nabla \hat{L}(x_i, y_i, z_i, \theta) = -2(y_i - g_{\theta}(\dot{p}, x_i)) g_{\theta}'(\ddot{p}, x_i), \qquad \dot{p}, \ddot{p} \sim \hat{F}(p|x_i, z_i)$$

(Hartford, Lewis, Leyton-Brown, Taddy: Deep IV, ICML 2017)

## Validation and model tuning

We can do OOS causal validation

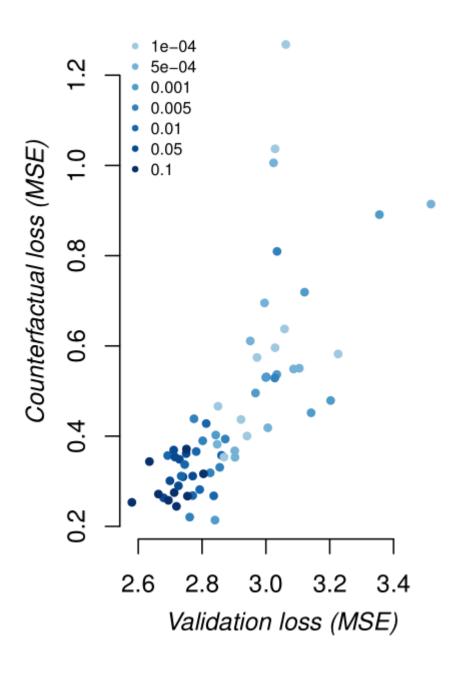

Leave-out deviance on first stage

$$\sum_{i \in LO} -\log \hat{f}(p|x_i, z_i)$$

Leave-out loss on second

$$\sum_{i \in IO} (y_i - \int g_{\theta}(p, x_i) d\hat{F}(p|x_i, z_i))^2$$

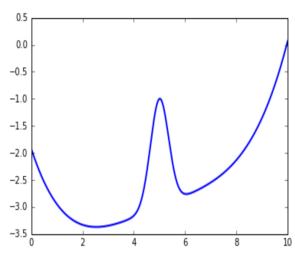

You want to minimize both of these (in order).

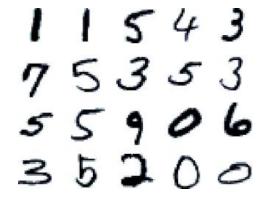

## A pricing simulation

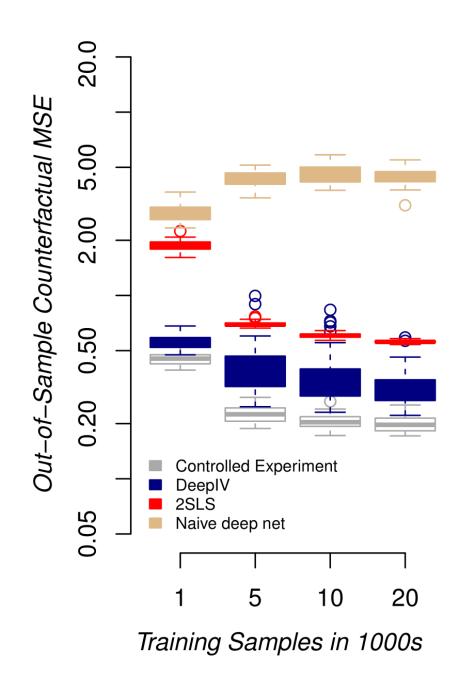

$$y = 100 + s\psi_t + (\psi_t - 2)p + e,$$
  
 $p = 25 + (z+3)\psi_t + v$   
 $z, v \sim N(0, 1) \text{ and } e \sim N(\rho v, 1 - \rho^2),$ 

Customer type 's'

### Deep Neural Networks

Deep nets are not nonparametric sieves The 1<sup>st</sup> layer is a big dimension reduction For example,

word embedding for text

matrix convolution for images

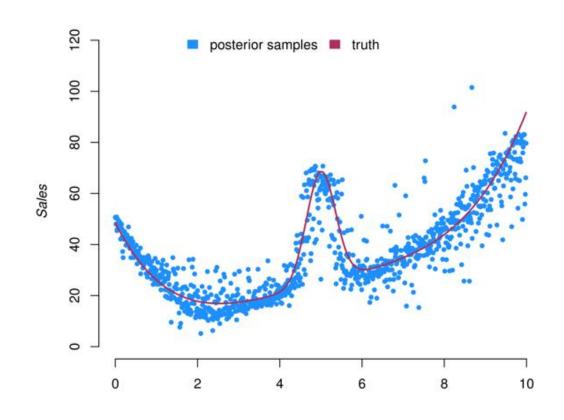

# Inference? Good question

**Data Splitting** 

Variational Dropout

**Quantile Regression** 

# Data Split

Fit DNNs that map from inputs to outputs  $\eta_k(x)$ , k = 1 ... KUse out-of-sample  $x_i$  to obtain 'features'  $\eta_{ik} = \eta_k(x_i)$ 

Possibly do PCA on  $\eta_{ik}$  to get a nonsingular design

Regress  $y_i \sim \alpha + \beta_1 \eta_{i1} + \beta_2 \eta_{i2}$  ... and use Huber-White SEs

This can be used to get var(E[y|x])

## Variational Bayes and Dropout

VB fits q to minimize  $\mathbb{E}_{q}[\log q(W) - \log p(\mathbf{D}|W) - \log p(W)]$ 

We train with dropout SGD:

At each update of weights  $\omega$ , use gradients for  $w = \xi \omega$ ,  $\xi \sim \text{Bern}(c)$ 

This corresponds to VB under

$$q(W) = \prod_{l} \prod_{k} c \mathbb{1}_{[W_k = \Omega_k]} + (1 - c) \mathbb{1}_{[W_k = 0]}$$

This works to get var(E[y|x])

# Quantile Regression

Instead of targeting MSE or logit loss, minimize quantile loss functions

$$L_q = q(y-t)1_{y>\tau(x)} + (1-q)(t-y)1_{y<\tau(x)}$$

Where q is your desired probability and  $\tau(x)$  is the quantile function Better yet, architect a net to fit multiple quantiles at once...

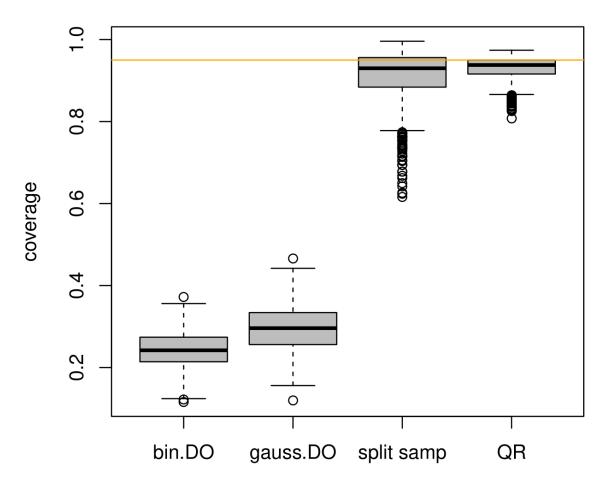

This can be used to get prediction intervals for  $y \mid x$ 

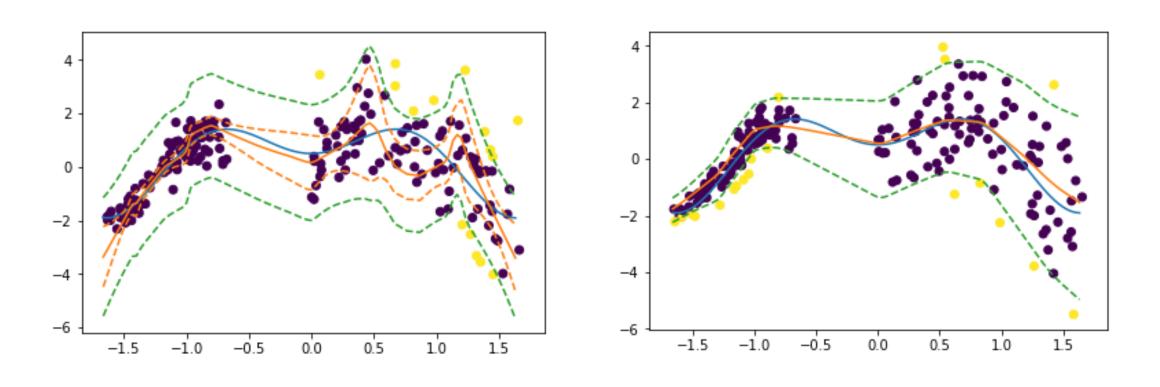

#### Million Song Dataset

- A dataset of a million songs
- Inputs are timbre features
- Output is the release year
- Test and train are split to have no overlap on artists

#### *Prediction interval coverage around random x*

# If you want prediction intervals, you should probably use quantile regression

For Confidence Intervals sample splitting can't be beat

#### Economic Al

The ML doesn't create new economic insights or replace economists It automates and accelerates subjective labor-intense measurement

- Instruments are everywhere inside firms
- With reinforcement learning there will be even more
- Reduced form econometrics is low fruit; structural econometrics is next
  - > Need to link long term rewards to short term signals

#### **Business Al**

Deep learning revolution: good low-dev-cost off-the-shelf ML As the tools become plug-n-play, teams get interdisciplinary The next big gains in Al are coming from domain context

- Use domain structure to break questions into ML problems
- Don't re-learn things you already know with baby AI
